The humidity output of a circle system was raised to 28 mg H2O/l by the use of a modified rotating wick vaporizer placed in the center of the soda lime canister and coaxial inspiratory and expiratory limbs. Both the fresh gas inflow and the expired gases passed through the lime and reached a compartment below it. The bag/ventilator connector, bearing a pressure relief valve, opened on the lateral wall of that compartment. Gases returning to the inspiratory valve passed: (1) through a tube in the

canister connecting the inferior compartment to the **vaporizer** above water level, (2) through the upper portion of the **vaporizer** and around the rotating wick, and (3) through a **tube** emerging from the top of the **vaporizer** to reach the inspiratory valve. Thus inspired **gases** were humidified by the rotating wick constantly replenishing its water content warmed by the reaction of neutralization. The use of coaxial inspiratory and **expiratory limbs reduced water condensation** outside the canister.

In humans, anesthetic uptake in a closed system with constant arterial concentration has been shown to be inversely proportional to the square root of time. A practical method for quantitative dosage of volatile anesthetic was derived from this. The method was evaluated in nine dogs anesthetized with a closed circle system using halothane and isoflurane. A unit dose (UD) of anesthetic was calculated in milliliters of **vapor** which was converted to milliliters of **liquid** and repeatedly administered into the **expiratory limb** between the squares of integer units of time (0-1, 1-4, 4-9 minutes, etc). The UD was derived as follows: $UD = 2 f MAC \times \lambda B/G \times 2 (kg)^{3/4}$, where f MAC was the desired alveolar concentration, $\lambda B/G$ the blood-gas partition coefficient, and $2 (kg)^{3/4}$ was an approximation of cardiac output. The method resulted in a stable plane of anesthesia and permitted continuous monitoring of O2 consumption. There was no significant difference between predicted and measured values of O2 consumption, cumulative doses, or alveolar concentrations at 9 and 16 minutes of anesthesia.

ABSTRACT: Breathing circuits for medical **respiratory** devices which have an inspiratory **conduit** for delivery of respiration-related aeriform substances to a patient, may also have a **expiratory conduit**, and, in any case are arranged to communicate with a patient interface, such as a wye (14), and have heating means for respiration-related aeriform substances in at least the inspiratory **conduit**. The heating means may be a heated- **liquid heating tube** (11) within at least the inspiratory **conduit** or an electrical heating wire (38) on or in an inspiratory **conduit** comprising **respiratory** hose (37). The **tube** is in circulatory relationship with a heated- **liquid** reservoir (13) and is arranged internally to contain heated **liquid** (30) from the reservoir, and to transfer heat from the **liquid** --by radiation and conduction from the **tube wall**--to the substances in the **conduit**. **This transferred heat tends to inhibit or to control formation of dangerous aqueous condensate** from the substances by compensating heat losses they otherwise sustain, enhancing their capacity to retain water **vapor** and providing an intra-**conduit** environment in which the condensate is unlikely to form. A manifold (12) enables the **tube** to extend to the **expiratory conduit**.

FINANCIAL ADVANTAGES OF USING ISOFLURANE IN A CLOSED CIRCUIT

AUTHOR: BOULOGNE P (Reprint); DEMONTUOX M H; COLIN D; FEISS P

AUTHOR ADDRESS: DEP D'ANESTHESIE-REANIMATION, HOPITAL UNIV DUPUYTREN, F 87042 LIMOGES**FRANCE

DOCUMENT TYPE: Article

RECORD TYPE: Abstract

LANGUAGE: FRENCH

ABSTRACT: The present study was designed to assess whether isoflurane requirement was significantly affected by fresh **gas flow** in a closed-**circuit** system. Sixty patients scheduled for orthopaedic procedures were randomly assigned into three groups. In group A (n = 20), anaesthesia was conducted with a fresh **gas flow** of 482.5 +/- 186.6 ml .cntdot. min-1, corresponding to the patient's metabolic demand. In group B (n = 20), the fresh **gas flow** was 2000 ml .cntdot. min-1. In group C (n = 20), it was adjusted to the ventilation minute, i.e. 7145 +/- 986 ml .cntdot. min-1. Artificial ventilation was conducted using a tidal volume of 10 ml .cntdot. kg-1 and rate of 10 to 12 c .cntdot. min-1. Anaesthesia was induced after 10 min denitrogenation with fentanyl (4 .mu.g .cntdot. kg-1), thiopentone (4 mg .cntdot. kg-1) and vecuronium (0.1 mg .cntdot. kg-1). FIO2 was then brought to 0.5 in nitrous oxide and was monitored continuously using a polarographic oxymeter. **Liquid** isoflurane was injected in the **expiratory limb** of the **circuit** using an electrical syringe driver. Alveolar concentration of isoflurane was set at 0.92 vol.

% according to Lowe and Ernst [5]. Statistical analysis was carried out using Student's test for means. Anaesthesia lasted 138 \pm 88.3 min in group A, 125.5 \pm 45.1 min in group B and 146.5 \pm 50 min in group C, no difference being significant. The requirements in **liquid** isoflurane for the first hour were 5.85 \pm 1.32 ml in group A, 10.75 \pm 1.12 ml in group B and 67.15 \pm 19.51 ml in group C. The total isoflurane consumption reached 11.32 \pm 6.73 ml in group A, 19.20 \pm 7.12 ml in group B and 157.20 \pm 40.41 ml in group C. The cost of isoflurane during the first hour (in US dollars; 1 US\$ = 6,14 FF) was 4.30 \pm 0.97 in group A, 7.79 \pm 0.93 in group B and 49.32 \pm 14.33 in group C. The total cost reached 8.28 \pm 4.94 in group A, 14.10 \pm 5.23 in group B and 115.47 \pm 29.68 in group C. The difference in consumption and expense between groups A, B and C were significant ($p < 0.001$). As isoflurane is 4.4 times more expensive than enflurane and 9.7 more than halothane, the dramatic saving with closed-**circuit** anaesthesia led to save a large sum of money, thus compensating the expenses for **gas** and **vapour** analysers which increase the security of low **flow** anaesthesia.

Abstract (Basic): US 20040244804 A1

NOVELTY - A nasal cannula (100) comprises:

(i) a manifold including a chamber (10), a **gases** inlet (16) to engage an inspiratory **conduit**, an outlet (12) to engage an **expiratory conduit** and a low resistance path for the **gases** through the chamber from inlet to outlet; and

(ii) nasal prongs (116, 118) in **fluid** communication with the chamber with each prong equidistant from the inlet

DETAILED DESCRIPTION - A nasal cannula (100) comprises:

(i) a manifold including a chamber (10), a **gases** inlet (16) to engage an inspiratory **conduit**, an outlet (12) to engage an **expiratory conduit** and a low resistance path for the **gases** through the chamber from inlet to outlet; and

(ii) nasal prongs (116, 118) in **fluid** communication with the chamber with each prong equidistant from the inlet.

The cannula includes a strap or an infant bonnet to hold the prongs in place in the nares of the neonate.

An INDEPENDENT CLAIM is included for a system for delivering **respiratory gases** in a neonatal infant comprising the nasal cannula.

USE - For delivering **respiratory gases** to neonatal infants (claimed).

ADVANTAGE - The cannula is equally applicable for patients of all sizes and the design is easily scalable. The inlet manifold has a notch or indentation in its uppermost portion between the two nasal prongs designed such that there will be no contact with the septum. This is in contrast with prior art where contact with the septum resulted in irritation and pressure necrosis. There is some **flow** flowing directly from the inlet manifold to the outlet manifold. This ensures that the deadspace or tidal volume is limited to the volume of the prongs. This configuration results in minimum build-up of expired CO2 and also **reduces** any opportunity for **condensation** in the cannula.

DESCRIPTION OF DRAWING(S) - The figure shows a block diagram of continuous positive air pressure system.

chamber (10)
gas outlet (12)
gas inlet (16)
nasal cannula (100)
nasal prongs. (116, 118)

Abstract (Basic): US 20040220534 A1

NOVELTY - A medical device comprises **conduit** for **fluid** comprising a wall made of hydrophobic **polymer** with outer layer composed of medical grade **hydrophilic thermoplastic** polyurethane and antimicrobial compound (I) disposed on outer surface of wall. (I) comprises a phosphorus-based glass having a metal substantially dispersed on it. The wall and the outer layer are formed by extrusion.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are included for the following:

- (1) manufacturing of the medical device;
- (2) a system for making the medical device.

USE - As a medical device, e.g. endotracheal **tube**, catheter, stent, feeding **tube**, **breathing circuit**, intravenous **tube**, **circuit**, airway accessory, connector, adapter, filter, humidifier, nebulizer, and prosthetic (claimed) for used around or inserted into a living body.

ADVANTAGE - The antimicrobial layer on the device **reduces** the incidence of ventilator-associated pneumonia without extensive reliance on large doses of antibiotics, without extensive reliance on suctioning and without requiring additional activities on the part of clinician; and **reduces** production cost.

DESCRIPTION OF DRAWING(S) - The figure shows a plan view of a medical device.

medical device (100)
conduit (102)
inflate cuff (104)
wall (112)
lumen. (116)

Abstract (Basic): EP 1129743 A2

NOVELTY - The filter has a housing with an inlet port and an outlet port for connection to respective breathing tubes . A gases space lies between the inlet and outlet ports and gases pass across the gases

space from the inlet port to the outlet port in use. A filter media (7) spans the **gases** space dividing the **gases** space into an inlet chamber and an outlet chamber. **Gases** passing from the inlet port to the outlet port pass through the filter media.

DETAILED DESCRIPTION - A surrounding outer wall (10) formed by cover members (14) surrounds the housing apart from the inlet port and outlet port and is spaced from the wall of the housing. One or more air pockets (11,12) are created between the outer wall and the housing. The cover members are snap-fitted together. The air pockets insulate the housing from ambient conditions.

USE - E.g. as an anti-bacterial filter in **circuits** providing **breathing** assistance and/or administration of anaesthetics during surgical procedures.

ADVANTAGE - **Reduces** possibility of **condensation** build-up in the filter.

DESCRIPTION OF DRAWING(S) - The drawing shows a cross-sectional view of the filter.

Filter media (7)
Outer wall (10)
Air pockets (11,12)

Patent Details:

Patent No	Kind	Lan Pg	Main IPC	Filing Notes
US 6095986	A	17	A61B-005/08	

Abstract (Basic): US 6095986 A

NOVELTY - An endotracheal **airway** adapter has windows from thin low high capacity plastic that rapidly equilibrates to the temperature of the warm moist **gases** in the patient **breathing circuit**. An anti-fog surfactant coats the windows and increases the wetting tension of the surface it covers as windows are placed in the **respiratory** airstream of a patient.

DETAILED DESCRIPTION - An endotracheal **airway** adapter for use in a patient's **respiratory** airstream near patient's mouth during

quantitative measurement of the concentration of the constituents of the patient using a **respiratory gas** analyzer (40) having infrared transmission and detection devices disposed in a housing which receives the **airway** adapter, comprises tubular portions, a pair of plastic optical windows (20), and a non-toxic anti-fog surfactant. The tubular portions have a **material** that is slightly deformable and has oppositely disposed openings in a width-wise direction. It lies on an optical path between the infrared transmission and detection devices when received by the **gas** analyzer housing (30). The plastic windows are respectively disposed over the openings of the tubular portion to form an airtight seal so that they are at a predetermined distance during the process. The windows pass infrared energy from the infrared transmission device to the detection device. The non-toxic surfactant treats the windows to prevent fogging when the windows are placed in the patient's **respiratory** airstream.

An INDEPENDENT CLAIM is also included for a method for forming the endotracheal **airway** adapter comprising respectively disposing the thin plastic windows in a widthwise direction which lie on an optical path between the infrared transmission and detection devices where infrared is passed. The windows are then treated with the non-toxic anti-fog surfactant to prevent fogging of the windows when they are placed in the patient's **respiratory** airstream.

USE - As an anti-fog **airway** adapter for use with a mainstream **respiratory gas** analyzer to prevent fogging by the patient's breath.

ADVANTAGE - The cheap and disposable **airway** adapter prevents water **condensation** which may **reduce** signal strength of the infrared energy, thus resisting fogging by shedding any **liquid** which might obstruct the optical path during **respiratory gas** analysis.

DESCRIPTION OF DRAWING(S) - The figure shows a perspective view of a mainstream infrared **gas** analyzer and a disposable **airway** adapter.

Optical windows (20)

Gas analyzer housing (30)

Gas analyzer (40)

pp; 17 DwgNo 1/8

Technology Focus:

TECHNOLOGY FOCUS - **POLYMERS** - Preferred Components: The tubular portion is formed from a **material** including a polycarbonate, styrene acrylonitrile, or aluminum. The windows are formed from a **material** including **polyester**, polypropylene, or polyethylene. It comprise a single plastic layer impregnated with the anti-fog surfactant to form an anti-fog film of 1-1.5 mil thick. A heat seal adhesive forms the airtight seal between the anti-fog film and the tubular portion. The thin plastic windows has a stretched sheet of **polymer** film. The adapter has a pair of frames to which the stretched sheets are heat sealed to form the respective window frame assemblies to be placed in the oppositely disposed openings.

INSTRUMENTATION AND TESTING - Preferred Method: A thin copper layer is disposed between the anti-fog film and the tubular portion to distribute the heat from the infrared transmission device over the tubular portion surface. A surfactant has a solution, which forms a layer over the windows when poured into the **airway** adapter. The solution is then drained followed by drying the windows in warm air. A **tube** is heat shrunk to cover the disposed openings in the tubular portion. A drum band is disposed in the window frame assemblies to hold them in place, and a **tube** is heat shrunk about the tubular portions to cover the respective oppositely disposed openings.

Abstract (Basic): WO 8911245 A

A patient link (20) receives the **gases** from the patient's **airway circuit** (11) and a **vaporisation** section (30) vaporises condensed moisture in the sample. A separator section (40) allows the **vaporised** moisture component of the sample to exit the patient interfacing system (10) before the **gas** sample reaches the monitoring instrument (12).

A filter (70) may also be utilised to prevent condensed moisture, particulates and **liquids** from entering the monitoring instrument (12). The patient interfacing system provides a reliable, cost effective and efficient means for delivering **gas** samples to a monitoring instrument which **reduces** or prevents water **condensation** inside the **gas** analysis portion of the monitoring instrument (12).

USE - For sampling the inspired and expired **gases** of a patient and removing moisture from the sample.

1/5

SZ TR TZ UG ZM ZW

Abstract (Basic): WO 200511785 A1

NOVELTY - A humidified gas delivery treatment apparatus comprises a
housing; a pressurized gases supply within the housing; a pressurized
gases outlet in the housing in fluid connection with the pressurized
gases supply and adapted to make fluid connection with an inlet of a
humidifier in order to provide gases flow to the humidifier; and filter
(100) on or over the inlet of the humidifier to filter the gases
entering the humidifier.

DETAILED DESCRIPTION - An INDEPENDENT CLAIM is also included for a
humidifier chamber for use with a gases humidification apparatus
comprising a container with a surrounding wall and top and an open

bottom; a heat conductive base enclosing the open bottom of the container; a **gases** inlet to the container; a **gases** outlet to the container; and filter on or over the inlet to the container to filter the **gases** to the container.

USE - For use in humidified **gases** delivery treatment (claimed).

ADVANTAGE - The combined humidifier and continuous positive **airways** pressure machine is manufactured and assembled such that the humidifier chamber may be removed for cleaning, replacement or refilling easily and quickly. When the humidifier chamber is separated from the continuous positive **airways** pressure machine, the filter may also be removed for cleaning or replacement quickly and easily.

DESCRIPTION OF DRAWING(S) - The figures show a perspective view of a water chamber and continuous positive **airways** pressure (CPAP) machine and an underneath view of the water chamber including the filter of the invention.

Water chamber (2)
CPAP machine (3)
Passage (4, 7)

pp; 23 DwgNo 1, 4/8

Technology Focus:

TECHNOLOGY FOCUS - INSTRUMENTATION AND TESTING - Preferred Components: A humidified **gases** return in the housing is adapted to make **fluid** connection with an outlet of the humidifier in order to receive humidified **gases** from the humidifier. A patient outlet in the housing is in **fluid** connection with the humidified **gases** return in order to receive humidified **gases** from the humidified **gases** return and provide humidified **gases** to the patient outlet. The patient outlet is in **fluid** connection with or adapted to make **fluid** connection with a **breathing conduit** for delivery of humidified **gases** to a patient. The humidifier is a heatable water chamber. The delivery treatment apparatus includes a chamber heater connected to the housing. The housing includes a humidifier engagement locating the humidifier adjacent the chamber heater. The chamber heater is adapted to **vaporize liquid** water in the water chamber in order to provide water **vapor** to the **gases flow** passing through the water chamber. The **humidification** chamber has a base. The chamber is engageable with the humidifier engagement via a single motion. The single motion of engagement urges the base of the **humidification** chamber adjacent and in contact with the chamber heater and makes a first **fluid** connection between the pressurized **gases** outlet and the humidifier inlet and makes a second **fluid** connection between the humidified **gases** return and the humidifier outlet. The first and second **fluid** connections are made in the direction of the single motion. The patient outlet includes a connector for receiving a **breathing** hose and auxiliary electrical connection plug(s) or socket(s) or pneumatic connection plug(s) or port(s) for a simultaneous connection when connecting a **breathing circuit** having complementary electrical and pneumatic connectors.

Abstract (Basic): WO 200458064 A2

NOVELTY - Collection of a sample of non-gaseous aerosol in exhaled breath, comprises inhaling a breath of air through a filter to remove ambient aerosols from the breath of air; and exhaling the breath of air through a collector and collecting aerosols from the exhaled breath.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are also included for:

(a) an aerosol collector apparatus for collecting aerosol from exhaled breath of a test subject, comprising an aerosol collection chamber with a collection surface for collecting aerosol particles and/or droplets from exhaled breath; a conduit for channeling the exhaled breath from the test subject to the aerosol collection chamber; and a pre-collection filter positioned in close enough proximity to the aerosol collection chamber to accommodate filtering ambient air inhaled by the test subject that is composed in the exhaled breath of the test subject; and

(b) a method to assure reproducibility of the collection of non-gaseous substances suspended in exhaled breath from a human or animal test subject, comprising providing a removing mechanism to

eliminate all suspended non-gaseous particles and liquid aerosol droplets from ambient air drawn into an inlet conduit, and conducting the cleaned intake air within the conduit to a first connecting unit to the test subject's respiratory airway, and providing a first one-way valve causing air to flow in a direction from the inlet conduit to the first connecting unit, the first one-way valve being situated at any effective location in the inlet conduit, and causing the subject to inhale the cleaned intake air, and conducting the consequent exhaled breath through an exhalation conduit, and providing a second one-way valve causing air to flow in a direction from the first connecting unit through the exhalation conduit, the second one-way valve being situated at any effective location in the exhalation conduit, thus eliminating substances external to the test subject from being inhaled by the test subject, and assuring that all non-gaseous substances suspended in the exhaled breath comprise only those arising from the test subject's respiratory system.

USE - For collecting a sample of non-gaseous aerosol (e.g. analyte) in exhaled breath from a human or animal test subject (claimed) for diagnostic purposes.

ADVANTAGE - The method is comparable from one test to another, and can be used to standardized reference values for useful breath aerosol analytes.

DESCRIPTION OF DRAWING(S) - The figure is an isometric view of an electrostatic breath aerosol analyte collector.

Main housing (12)

Mouthpiece (14)

Conduit (20)

End of conduit (32)

Flow meter (80)

pp; 52 DwgNo 1/13

Technology Focus:

TECHNOLOGY FOCUS - INSTRUMENTATION AND TESTING - Preferred Method: The method includes controlling flow rate of the exhaled air through the collector to a desired flow rate; assisting the exhaled breath of air through the collector with a pump; and inhaling the breath of air through a first conduit (20) that contains the filter and exhaling the breath of air through a second conduit that contains the collector. The method comprises enhancing a property of the aerosol in the exhaled breath by charging the aerosol with an electrostatic charge; and creating a different electrostatic charge on a collection component to create an electrostatic attractive force between the aerosol and the collection component and applying such electrostatic force to attract the aerosol to the collection component. The method includes enhancing mass of the aerosol in the exhaled breath by super cooling air and water vapor in the exhaled breath to cause condensation of water vapor on the aerosol; and applying centrifugal force to the aerosol enhanced with the additional mass of the condensed water to increase probability of contact of the aerosol with a collection surface. Preferred Component: The aerosol collector apparatus includes an ionizer system in the conduit for ionizing gas in the exhaled breath, and where the collection surface is charged with an electrostatic voltage. The aerosol collector apparatus includes at least one valve positioned to control flow of exhaled breath through the conduit; at least one flow meter (80) positioned to measure flow rate of the exhaled breath through the chamber; and a wiper, which is positioned slidably on the collection surface for wiping the collected particles

and/or droplets off the collector surface. The apparatus includes a vortex generator in fluid flow relation with the collection chamber. The apparatus includes a mouthpiece (14) connected in fluid-flow relation to the conduit; and an ionizer assembly positioned in the conduit upstream from the collection surface. The connecting unit can be respiratory facemask, a respiratory mouthpiece, a conduit such as an endotracheal tube inserted within the subject's upper airway, a tracheostomy portal, a component of a ventilator breathing circuit, and a component of any other respiratory support device.

Patent No	Kind	Lan	Pg	Main IPC	Filing Notes
US 5988164	A		11	A61M-016/00	

Abstract (Basic): US 5988164 A

NOVELTY - **Respiratory device** has inspiratory and **expiratory conduits** with a heating tube (11) within a portion of each conduit. A manifold (12) has a cross member (24) extending between parts (22,23) of the inspiratory and **expiratory conduits** with an internal wall (25) providing a barrier between the conduits (22,23), and the wall having a port (28) for transition of the heating tube (11) between the two conduits.

DETAILED DESCRIPTION - ALSO CLAIMED is the device above for transit of a humidified aeriform substance in which the heating tube contains heated liquid (30) so as compensate for heat loss of the aeriform substance to enhance the capacity to retain water vapor and inhibit condensation; the latter arrangement in which the inspiratory and **expiratory conduits** are connected to a 'Y' junction communicating with a common airway, and the latter arrangement in which the relative humidity in the inspiratory conduit is sensed and used to control a pump circulating heated liquid in the heating tube (11). AN INDEPENDENT CLAIM refers to a **breathing circuit** in which an electric heating wire heats an inspiratory conduit with the heating controlled in response to the output of a sensor of the relative humidity of the aeriform substance in the inspiratory conduit.

USE - In apparatus for ventilation and therapy of the lungs, administration of anesthetics and other medicaments, etc.

ADVANTAGE - Provides safe control of the relative humidity of the aeriform substance to prevent condensation which can be dangerous to

the patient.

DESCRIPTION OF DRAWING(S) - The figure shows the **respiratory** system
heating **tube** (11)
'Y' connector (14)
inspiratory **conduit** (17,18,22)
expiratory **conduit** (19,20,23)
pump (29)
heated water (30)
humidity sensor (33)
pp; 11 DwgNo 2/8

Extension Abstract:

EXAMPLE - In the EMBODIMENTS each **conduit** comprises first and
second hoses connected in series by the respective section of the
manifold. The heated **liquid** in the heating **tube** is water from a
reservoir, circulated by a pump (29) controlled by a humidity sensor(33).

Abstract (Basic): WO 9719719 A

The system includes a conventional mechanical ventilator (84) and **breathing circuit** (70,80) connected to the patient (62) by a patient connector (64) and one-way valves (66,68). An additional **circuit** (896,90,94) including a pump (92) and flexible reservoir (88) is also connected to the ventilator to form a closed **gas circuit**. A **gas** injector (82) introduces oxygen during ventilation.

Therapeutic chemicals may be introduced directly into the patient's lung or via a nebuliser (98) in the **circuit**. An absorber (72) removes carbon dioxide from the expired **gas**, but allows any exhaled therapeutic chemicals to be carried round the **circuit** and reintroduced to the patient.

ADVANTAGE - The system minimises losses to the environment of chemical substances which may be expensive, environmentally sensitive and potentially damaging to parts of the associated mechanical ventilator.

Abstract (Basic): DE 3305159 A

The inhalation device has a housing (1) containing a **fluid vapouriser** (2) together with a removable mouth piece (3). In order to prevent unwanted re-entry of **vapour** into the **vapour circuit**, the **vapouriser** has a funnel shaped extension piece (5) which widens out upwards towards the mouth piece.

The mouth piece has an outlet port (12) and is further provided with a condensate rib (14) positioned near to the inner wall (13) of the housing and parallel to it and having a face (4) opposite the extension piece. The **lower** edge of the condensate rib is positioned within the upper edge (16) of the extension piece. Heating of the **vapouriser** unit is provided by an element (9).

Abstract (Basic): US 20030070680 A1

NOVELTY - The water permeable **material** is forced through concentric extruding heads of a blown film extruder, through which air is blown to create a thin walled **tube** (5) in the form of a flat band. The thin-walled **tube** is converted to the hydrogen ion form, dried and

bathed in methanol to swell the flat band into a tubular shape.

DETAILED DESCRIPTION - AN INDEPENDENT CLAIM is also included for dryer or humidifier.

USE - For manufacturing thin-walled permeable membrane tubing such as **NAFION tube** used in drier/humidifier (claimed) used to dry or humidify **breathing gases** supplied to patient.

ADVANTAGE - As the **tube** is thin-walled and is of non-self supporting nature, the tubing can be folded easily, thus the **tube** can be fed to the outer protective mesh easily.

DESCRIPTION OF DRAWING(S) - The figure shows a cross-sectional view of the thin-walled **Nafion** tubing.

Abstract (Basic): US 20030111077 A1

NOVELTY - A shroud (28), arranged about a portion of a **humidification mechanism** (18), includes an **expiratory gas inlet** (26) and an **expiratory gas outlet** (30). A patient **expiratory gas tube** (24) is attached to the **expiratory gas inlet** such that **expiratory gas** from a patient flows into the shroud through the **expiratory gas inlet** and

exits the shroud through the **expiratory gas** outlet.

DETAILED DESCRIPTION - An INDEPENDENT CLAIM is also included for a shroud.

USE - For humidifying **gases** within a mechanical ventilator used for a patient.

ADVANTAGE - **Reduces condensation** within tubing, and ensures effective **humidification** of **gases** within ventilating system.

DESCRIPTION OF DRAWING(S) - The figure shows the schematic representation of inspiratory air providing system.

Humidification mechanism (18)

Patient **expiratory gas tube** (24)

Expiratory gas inlet (26)

Shroud (28)

Expiratory gas outlet (30)

					CIP of patent US 5377670

Abstract (Basic): US 5735266 A

The **tube** (1) comprises an air impervious corrugated **tube** (2) for carrying conditioned **gases** and an outer casing (3) for insulating the corrugated **tube**. The corrugated **tube** is located within the casing and

has an outer diameter less than the internal diameter of the casing. The casing is greater in length than corrugated **tube** and is sealed at its ends to the ends of the corrugated **tube**.

The casing is in a slightly longitudinally compressed state relative to the corrugated **tube**, defining an insulating dead air space between the corrugated **tube** and the casing. The ratio of linear volumes of the casing and the corrugated **tube** are in the range of up to 10.0 to 1.0. The casing is of smooth sidewall construction and of a thickness which is equal to or less than the thickness of the corrugated **tube**.

USE - For use in a patient temperature conditioning system, eg for maintaining a prescribed temperature of a patient during an anaesthesia/surgical procedure or thereafter.

ADVANTAGE - The device stabilises the thermal gradient to **reduce** heat losses between the conditioned air and the surrounding atmosphere.

DE 19621541	C1		5	A61M-016/16	
US 6367472	B1			A61M-015/00	

Abstract (Basic): DE 19621541 C

This respirator machine humidifier has an outer casing, water supply, respiration **gas** supply and offtake line. **Humidification** is carried out by a bundle of **hydrophobic hollow fibres, which are permeable to water vapour, but not to liquid water**. The **gas** supply and off take are connected by the interior of the hollow fibre strands. In the novel unit, there are means of electrical heating around the hollow fibres (7) and along the length of their outer circumferential surfaces.

The hollow fibres are PTFE, polyurethane, polysulphone or porous glass sinter treated hydrophobically by a silicone.

USE - A humidifier with heater, for a respirator machine.

ADVANTAGE - Humidifiers raise the moisture level and if appropriate, the temperature of air for respiration, to suitable physiological levels. The humidifier has formerly been separate from

the respiration equipment, necessitating complicated interconnection and inconvenient handling. This unit integrates the **humidification**, **reducing** overall cost and improving convenience and compactness. The unit is easily constructed and relatively maintenance free. It can be placed directly in the respirator system inspiration line. The closed water system prevents contamination of the air line, and uses a bottle of sterile water. Though compact, the fibre system humidifies to a near constant level of 90-100% RH. Heating supplies a second purpose, it may be turned up briefly, for sterilisation purposes.

Abstract (Basic): GB 2277689 A

The heater for a device through which **gas flows in a breathing gas circuit**, comprises an electrical resistance heating element having a surface which is in thermal contact with a wall of the device such that its internal surface can be heated to **reduce condensation** within the device. The heater is separable from the device and contacts the external surface of the wall of the device.

The device and the heater are of frusto-conical shape, and the heater has an inwardly-extending flange at one end with a central aperture. The device has a male coupling that projects through the aperture, and the heater is retained on the device by a cooperating female coupling.

USE/ADVANTAGE - E.g. for medical and surgical devices. **Reduced condensation** build-up for **reduced** patient risk from bacterial accumulation.

Dwg.1/2

Abstract (Equivalent): GB 2277689 B

An HME or filter device through which **gas flows in a breathing gas circuit** and including a heater having an electrical resistance heating element, wherein the heater is separable from the device and has a surface in thermal contact with the external surface of a wall of the device enclosing an HME or filter element such that the internal surface of the wall of the device can be heated to **reduce condensation** within the device.

Abstract (Basic): GB 2268786 A

The tubing has an inner corrugated **tube** (32) and an outer flexible **tube** (34) extending along its length. The outer **tube** (34) is bonded to the corrugated **tube** where it contacts the corrugations (33) so that air is trapped between the corrugations. This insulates the tubing and **reduces condensation**.

The bonding between the **tubes** may be achieved by a solvent or adhesive or by heat treating the **tubes**. The corrugation may be by a helical reinforcement element wound around the outside of the **tube**. The inner **tube** may have an external layer of an insulating foam held in place by its resilience after being radially stretched.

USE - A tubing for connecting a humidifier to a tracheal **tube** or face mask.

US 5143060	A		10	A61M-016/22	CIP of application US 89363531
------------	---	--	----	-------------	--------------------------------

Abstract (Basic): US 5143060 A

The system for use with assisted human **breathing** systems includes an enclosure adapted to receive a granular **material** for absorption of carbon dioxide from the air exhausted from a patient using the system. An exhaust air inlet is provided to the device, and a return air outlet is provided from the device to the user. The exhaust air inlet and the return air outlet communicate through the granular **material** contained

within the apparatus. The enclosure which contains the granular **material** is insulated so that heat generated by the absorption of carbon dioxide onto the granular **material** is retained by the return air stream emitted from the enclosure.

Insulated tubing is connected between the device and the patient so as to **decrease** heat loss and **condensation** of moisture from the circulating air. The enclosure can isolate **breathing** gases from other parts of the system to prevent contaminated patient **gases** from contacting mechanical parts of an anaesthesia machine associated with the **breathing** system. The prevents contamination of the patient by **gases** that have been in contact with internal mechanical parts of the anaesthesia machine which have been in contact with **gas** breathed by prior patients.

USE - With recirculation type **breathing** systems for conditioning air to be supplied to a patient. E.g. in surgical operating rooms.

Abstract (Basic): US 5016628 A

Rebreather appts. has a disposable CO2 absorber comprising a flexible bag-shaped packet made of film **material** contg. granular CO2 remover.

Pref. an inlet with a check valve and a perforated outlet e.g. a disc or tube are provided. Pref. the bag is transparent and made of polyethylene.

ADVANTAGE - The flexible bag allows more surface area to be utilised, **reduces condensation** and allows the granules to move providing a more uniform flow path. The bag is less expensive to produce than rigid containers. (5pp Dwg.No.1/2)

Abstract (Equivalent): EP 453926 B

Apparatus for rebreathing gas characterised by granular means (5) for absorbing CO₂; and a flexible container (4) for containing the granular means (5), the container having an intake port (2) for the gas to enter the container and an exhaust port (6,7) for the gas to exit the container after the gas has flowed through the granular means.

ABSTRACT

PROBLEM TO BE SOLVED: To provide a **respiratory humidification** system capable of detecting and controlling humidity.

SOLUTION: A flow rate probe 19 used in a **humidification** system is disclosed. The flow rate probe is constituted to be arranged in a humidified gas flow provided for a patient in a hospital. The flow rate probe is designed to provide both temperature and a flow rate of a gas flow by incorporating two sensors, to enable accurate readings by **reducing** the occurrence of **condensation** on the sensors by a shape and alignment of this flow rate probe. A number of possible applications are disclosed wherein a flow rate sensor 35 is included in a humidity control system. This humidity control system provides the patient with a desired humidity level, and simplifies required user input. The flow rate sensor provides a controller with flow rate information used to determine certain possibly dangerous conditions (such as incorrect flow sensor placement, a **breathing** device disconnected, no water in a humidification chamber, or humidity out of required limits).

ABSTRACT

PROBLEM TO BE SOLVED: To perform low flow anesthesia by **reducing condensation** formed in an anesthetic **circuit** through suppressing the rise in temperature of a carbon dioxide absorbent and through **reducing evaporation** of moisture from the carbon dioxide absorbent, without increasing a decomposed compound.

SOLUTION: Low flow anesthesia, where the total supply of fresh **gas** containing oxygen and a volatile anesthetic in a closed circulation respirator system is less than or equal to 2 liter/min, is performed by radiating heat efficiently from the carbon dioxide absorbent which produces heat when absorbing carbon dioxide, by **reducing condensation** formed in the anesthetic **circuit** through suppressing the rise in temperature of the carbon dioxide absorbent to the minimum and through **reducing evaporation** of moisture from the carbon dioxide absorbent, and without increasing the decomposed compound produced by a reaction between the volatile anesthetic and the carbon dioxide absorbent.

Abstract (Basic): US 20040193101 A1

NOVELTY - A device for collecting condensed vapor and moisture from

a **gas directing conduit** (112) having an opening, comprises:

- (i) a lid (120);
- (ii) a reservoir (140) capable of forming a seal with the lid, and for receiving **vapor** and moisture; and
- (iii) a duct (114) having proximal and distal ends, the distal end (121) being in communication with the lid and the proximal end adapted for communication with the **conduit**.

DETAILED DESCRIPTION - An INDEPENDENT CLAIM is also included for a method of draining **fluid** from a **gas directing tube** or draining a heated wire **circuit**, comprising:

- (a) providing a **fluid** collection device;
- (b) creating an opening in the **gas directing tube**; and
- (c) inserting portion(s) of the **fluid** collection device into the opening in the **gas directing tube**, so that **fluids** within the **gas directing tube** may **flow** into the reservoir.

USE - For collecting condensed **vapor** and moisture from a **gas directing conduit** (claimed).

ADVANTAGE - The device provides for the condensate removal along a **gas directing conduit** or system at points other than between **gas directing conduit** connections or at terminal points of the **gas directing conduit**. Periodic aspiration of accumulated **liquid** from the apparatus without interruption of **gas flow** through the **gas directing conduit** may also be facilitated.

DESCRIPTION OF DRAWING(S) - The figure is a side view of the **fluid** collection device in contact with a **gas directing tube**, which is shown in cross-section.

Gas directing conduit (112)

Duct (114)

Lid (120)

Distal end (121)

Reservoir (140)

pp; 18 DwgNo 3/9

Technology Focus:

TECHNOLOGY FOCUS - INSTRUMENTATION AND TESTING - Preferred Components: The duct is capable of sealingly engaging the opening in the **conduit**. The duct in communication with the lid is integrally formed to the lid. The duct is sized to be capable of receiving a piercing mechanism. The device further comprises a retention mechanism capable of retaining the duct in position relative to the **conduit**. The retention mechanism encompasses a portion of the **conduit** to maintain the position of the device relative to the **conduit**. It is at least inside the **conduit** when the device is properly positioned. The duct has opening(s), which enable **fluid** to **flow** from the **conduit** into the reservoir.

Abstract (Basic): US 20040193100 A1

NOVELTY - A draining assembly (100) comprises a collection reservoir (104) in **fluid** communication with a piercing member (102) having a **fluid flow** path (108) through a portion of it and a retention mechanism (106) for maintaining the position of the reservoir relative to a **gas directing tube** (112).

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are included for:

(1) draining a ventilating system using the assembly comprising inserting the piercing member into the **gas directing tube** to create an opening in the **gas directing tube**, and securing the assembly to the **tube** so that **liquids** within the **tube** may **flow** into the collection reservoir; and

(2) draining a heated wire **circuit** using the assembly comprising inserting the piercing member into the **circuit** to create an opening in the **circuit**, and securing the assembly to the **circuit** so that **fluids** within the **circuit** may **flow** into the reservoir.

USE - For collecting condensed **vapor** and moisture from a **gas directing tube** (claimed).

ADVANTAGE - The drain assembly can be installed before or after **fluids** begin to **flow** through the **conduit**. The assembly need not to inserted between two **conduits** or break (i.e. separation) of one **conduit**. The assembly can be inserted into pre-existing **conduit** and provides the ability to install the drain assembly during use of **conduit** with minimal or no interruption of the **fluid flow** through the **conduit**. The assembly **reduces** leaks in the system.

DESCRIPTION OF DRAWING(S) - The figure shows a side of draining assembly in contact with **gas directing tube**.

draining assembly (100)
piercing member (102)
collection reservoir (104)
retention mechanism (106)

fluid flow path (108)
gas directing tube (112)
pp; 18 DwgNo 3/9

Technology Focus:

TECHNOLOGY FOCUS - INSTRUMENTATION AND TESTING - Preferred
Assembly: The piercing member comprises a **conduit**, where the **conduit** is capable of conducting **fluid** to the collection reservoir. The piercing member forms a portion of the **conduit**. The collection reservoir comprises a lid member having an opening, the lid member being in communication with the piercing member to allow **fluid** to **flow** through the opening into the collection reservoir. The piercing member or **conduit** has several openings to allow **fluid** to **flow** through a portion of it, where one of the openings allows for **fluid** in the **gas directing tube** to enter the assembly and one of the openings allows for the **fluid** to pass into the reservoir. The reservoir has an access port to allow for the aspiration of **fluid** from the reservoir. The access port is a normally closed opening in the reservoir capable of receiving a probe through which suction is selectively communicated to remove **fluid** from the reservoir. An evacuation **tube** is interposed between the normally closed opening of the reservoir and the interior of the reservoir. The retention mechanism encompasses a portion of the **gas directing tube** to maintain the position of the assembly relative to the **tube**. The retention mechanism comprises a clamp. The assembly comprises a sealing member to **reduce fluid** leaks from the **tube** or the assembly. The sealing member is disposed about a portion of the retention mechanism.

Preferred Method: The method of (1) further comprises aspirating **fluid** from the collection reservoir. The aspirating includes periodically aspirating accumulated **fluid** from the reservoir. The aspirating is performed by a probe. The aspirating includes a suction source. In (1) and (2), inserting the piercing member occurs at a low point along the **tube**.

Patent Details:

Patent No	Kind	Lan Pg	Main IPC	Filing Notes
JP 2000178009	A	7	C01B-013/02	

Abstract (Basic): JP 2000178009 A

NOVELTY - Oxygen enricher comprises **liquid-vapor separator (113)** for separating water in compressed air and draining unit for draining the separated water. Separator (113) is provided with a spiral **flow**

path and compressed air passing through the **flow** path is subjected to oscillation. The draining unit comprises an electromagnetic valve (115) which enables expansion of compressed air by instant switching.

DETAILED DESCRIPTION - Oxygen enricher (110) comprises compressed air supply unit (111) for supplying compressed air, condenser (112) for condensing compressed air, **liquid-vapor** separator for separating water in compressed air, draining unit for draining separated water, switching valve (117) for switching **flow** path of compressed air selectively, concentrated oxygen forming unit (118) for separating nitrogen and oxygen in compressed air and forming concentrated oxygen and controlling unit for adjusting oxygen concentration in the unit (118). **Liquid-vapor** separator is provided with a spiral **flow** path and compressed air passing through the **flow** path is subjected to oscillation. The draining unit comprises an electromagnetic valve. The compressed air expands by instant switching of the valve (115).

USE - For medical treatment such as for treating **respiratory** diseases and for supplying oxygen to the patient during an operation.

ADVANTAGE - Water droplets and impurities are effectively removed from the compressed air, in **liquid-vapor** separator. The rate of **flow** of compressed air is adjusted stably without blocking the switching valve, thereby easily controlling the concentration of oxygen.

DESCRIPTION OF DRAWING(S) - The figure shows block diagram of oxygen enricher.

Oxygen enricher (110)
Compressed air supply unit (111)
Condenser (112)
Liquid-vapor separator (113)
Electromagnetic valve (115)
Switching valve (117)
Concentrated oxygen forming unit (118)
pp; 7 DwgNo 1/7

Technology Focus:

TECHNOLOGY FOCUS - MECHANICAL ENGINEERING - Preferred Process:
Electromagnetic valve is operated before operating switching valve.
Preferred Valve: The switching valve is an orifice valve comprising an orifice plate. The valve is configured along the **flow** path of compressed air.

Abstract of GB2224957

A water trap, in the air line of a respirator for administration of anaesthetics or a mechanical breathing system, comprises a membrane 8 that allows passage of water into container 9 but prevents substantial passage of gas. The membrane may be formed of an absorbent material which forms a barrier to gas when saturated with water, for example, a polytetrafluorethylene based hydrophilic material. Alternatively the membrane may be formed of a material that will allow diffusion of water therethrough for example, a hydrogel supported on plastics netting. Container 9 has a valve or is removable for emptying.

Abstract of JP2193680

PURPOSE: To provide a patient in hospital with a humidification gas as needed, by forming a porous wall into a water compartment which provides a first path and also consists of a sheet-shaped porous material which is substantially included by a water compartment support means and mechanically reinforcing the porous material of the water compartment in order to resist the pressure on the water compartment support means. **CONSTITUTION:** A water compartment 30 consists of a porous seet material 40 which has sealed marginal parts 41, 42 and 43. The porous material 40 substantially has permeability to water vapor, but substantially impermeability to liquid water, for example it is made of a reinforced PTFE. To form the water compartment 30 consisting of a porous wall, the sheet material 40 is cut into a rectangle and folded, and the marginal parts, in order to form sealed marginal parts 41, 42 and 43, are rigidly anchored each other, for example by injecting a plastic material around the contact marginal parts.

Abstract of WO0048682

This invention is a heat, and moisture exchanger (960) including a gas permeable element (962) made of a fibrous media which traps the heat, the moisture from a patient's exhalant; which imparts heat, moisture to inspiratory gases as the patient inhales, conserving the patient's pulmonary heat and moisture. The media is made of a hydrophilic nylon polymer. The gas permeable element (962) can be formed entirely of mono-component fibers of the hydrophilic polymer or they may be a bi-component fiber having a sheath of the hydrophilic polymer with a thermoplastic core, e.g. polypropylene. The fibers are held together at their mutual points of contact with a bonding agent, e.g. polyester.

1492459 Humidifying respiratory gas
DRAGERWERK AG 27 June 1975 [27 June 1974] 27379/75 Heading A5T [Also in Division B1] A humidifier for respiratory apparatus comprises a tube 6 of material pervious to water vapour but impervious to water liquid the tube being surrounded by a container 5 forming a water jacket around the tube 6, the tube 6 providing a passage for inhalation air to the patient. A pump 10 circulates heated water through the container 5 from a reservoir 9. Coupled non-return valves (15, 16) Fig. 3 (not shown) may be disposed in the water supply and return conduits, the valves being closed during inhalation and opened during exhalation due to the response of the water in the circuit alternately to the inhalation and exhalation pressures of the gas in the tube 6. The material forming the tube 6 may be macroporous and hydrophobic or microporous and hydrophilic. The tube may have a star-shaped cross-section. A sheet 19 of the same material as the tube 6 is arranged downstream of the humidifier to prevent water entering the breathing passages in the event of a leak in the tube 6.

Abstract of EP0673668

A dehumidifying device is often used to protect measurement equipment from condensation during measurements of a flowing gas. A device (2), which does not need to be replaced, is achieved when a container (4) is filled with a hydrophilic material (6, 18) and connected to a moisture permeable element (20). When a gas flows through the device (2) via an inlet (14), a flow channel (12) and an outlet (16), the hydrophilic material (6, 18) absorbs moisture from the flowing gas. The absorbed moisture is released into ambient air via the moisture permeable element (20).

Abstract of JP6063141

PURPOSE: To provide a filter showing high microorganism elimination efficiency and low loss of moisture by consecutively placing hydrophilic base-material sheets and hydrophobic base-material sheets in the channel of a housing, and closely setting the hydrophilic base-material sheet to a connecting part of a exhaling line, and specifying the alcohol bubble point of a hydrophobic base- material to a particular value.
CONSTITUTION: The filter, which is stored in a housing 12 equipped with ports 13 and 14, is composed of a hydrophilic base-material sheet 11 and a hydrophobic base-material sheet 10 pleated together. A ventilator is connected to the port 14 in the hydrophilic base-material 11 side of this device. The port 13 in the hydrophobic base-material 10 side is connected to a patient who inspires and expires a gaseous matter from the ventilator, so that the hydrophobic base-material 10 is made to be having an alcohol bubble point of 710 mm (28 inches) H₂O or higher to eliminate microorganisms. The water, which flows penetrating through the hydrophobic base-material, is captured by the hydrophilic base-material sheet 11 and diffused to all over the same. Therefore, usage of additional humidifiers is avoided.

Abstract of GB2267840

A heat and moisture exchanger and filter for inclusion in an air line used in anaesthesia or patient ventilation comprises a housing having inlet and output ports (1) & (2), the interior (16) of the housing being of greater cross sectional area than either of said ports, and a heat and moisture exchange element (8) spanning the interior of the housing between the ports, said element (8) being in the form of a sheet of water-activated, hydrophilic polyurethane reticulated foam untreated with any hygroscopic or hydrophilic agent, the housing and element being so arranged that air flow is distributed uniformly of the surface of the element. The housing also encloses a filter element (7), of electrostatically charged polymer fibres able to retain bacteria, in close contact with element (8). In making element (8), a block of foam is cast in a polypropylene or polythene mould, sliced into sheets and die-cut to shape.

Abstract of GB2252515

A humidifier of small gases passageway volume (of the order of 50 ml gases space) has a heater 50 within a water containing envelope 30 having a microporous wall 40 common to the water space within the envelope and the gases space. This microporous wall is permeable to water vapour but not liquid water and the envelope is reinforced by a support which also directs the flow of gases over the surface of the envelope. The heater 50 is wound as a flat spiral to avoid the effect of gases or water vapour bubbles on heater performance temperature.

Abstract (Basic): US 20050056286 A1

Abstract (Basic):

NOVELTY - The breathable respiratory mask includes a patient interface having a body and a seal. The body includes a moisture permeable area. The interface is adapted to provide a sealed flow path for the flow of gases to a user.

USE - For delivering supply of gases to a user. For delivering artificial respiratory therapy to patients requiring respiratory

humidification treatment.

ADVANTAGE - Ensures enough compressive force on the mask cushion to provide an effective seal against the user's face. Allows for quick removal of the hollow body, thus enabling other treatments to be administered with minimal disruption to the user. Increases user comfort by reducing the compressive force of the patient interface on the user's face. Minimizes gas leakage from the mask.

DESCRIPTION OF DRAWING(S) - The figure shows the front view of the patient interface body.

Abstract (Basic): US 20040099268 A1

Abstract (Basic):

NOVELTY - A breathing circuit limb comprises an inlet, an outlet, and an enclosing wall defining a singular exhalation flow passage between the inlet and outlet, and a water vapor flow path from the exhalation flow passage to ambient air through the material. At least a region of the enclosing wall is of a material that allows the passage of water vapor without allowing the passage of liquid or respiratory gases.

DETAILED DESCRIPTION - An INDEPENDENT CLAIM is also included for an apparatus for forming a breathing conduit comprising a former on which a tube wall can be deposited and that advances the tube wall in advance axis and rotates at the advance direction, at least one film laying head that deposits a film on the former, a bead laying head laying a reinforcing bead on an overlap seam, an axial thread laying head fitted over and around the former and carrying thread feeds, and a rotator to rotate the axial thread laying head at the same speed as the expected rotation of the tube. The combined width of the film is wider than the pitch so that adjacent turns of the laid film overlap to form an

overlap scam.

USE - For the expiratory arm of a breathing circuit used in medical applications.

ADVANTAGE - The invention provides the public and medical profession with a useful choice. The material allows the passage of water vapor without allowing the passage of liquid water or respiratory gases.

DESCRIPTION OF DRAWING(S) - The figure shows a cross sectional elevational of a coaxial breathing circuit.

 Abstract (Basic): EP 1166814 A2
 Abstract (Basic):
 NOVELTY - The conduit has an elongated heating element (110)
 covered with an inner hydrophobic insulating layer and an outer
 hydrophilic layer. The heating element is located in the conduit and
 associated at least in part with a portion of hydrophilic material
 (108), there being no means for direct supply of water or fluid to the
 hydrophilic material from outside the conduit.
 DETAILED DESCRIPTION - An INDEPENDENT CLAIM is included for a
 breathing circuit.
 USE - In medical applications for administering breathing gases to
 patient.
 ADVANTAGE - Reduced formation of condensation.
 DESCRIPTION OF DRAWING(S) - The drawing shows a cross sectional
 view of the conduit.

 Abstract (Basic): EP 1153627 A2
 Abstract (Basic):

NOVELTY - The coaxial breathing circuit component includes an enclosing wall defining a gas passage between an inlet and an outlet. The predetermined region of the enclosing wall consists of a hydrophilic material that allows the passage of a water vapor without allowing the passage of water or respiratory gases.

DETAILED DESCRIPTION - An INDEPENDENT CLAIM is also included for a breathing circuit conduit manufacturing apparatus.

USE - Used in medical application.

ADVANTAGE - Enables reduction of formation of condensation on inside wall of conduit by maintaining or elevating the temperature of the gases flowing along conduit wall.

DESCRIPTION OF DRAWING(S) - The figure shows the partial cross-section side elevation of coaxial breathing circuit.

RECORD TYPE: Abstract

LANGUAGE: English

ABSTRACT: A breathing circuit component includes an inlet, an outlet and an enclosing wall. The enclosing wall defines a gases passageway between the inlet and the outlet. At least a region of the enclosing wall is formed from a breathable material that allows the passage of water vapor without allowing the passage of liquid water or respiratory gases. The breathing circuit component may be the expiratory limb of a breathing circuit.
